# Repeated induction <br> of testicular maturation and spermiation, alternating with periods of feeding and growth in silver eels, Anguilla anguilla (L.) 

Jens Dollerup \&̛ Cbr. M. Graver<br>The Danish Institute for Fisheries and Marine Research, Charlottenlund Castle, DK-2920 Charlottenlund, Denmark

#### Abstract

Sexual maturation was induced in a batch of 95 male silver eels (Anguilla anguilla (L.)) with human chorionic gonadotrophin ( 500 IU on days 0 and 7 ). After spermiation the eels were given food (from day 118) and started to eat and grow. Later two further sexual maturations were induced (injections on days 179 and 186 and on days 400 and 407). During the last part of the experiment (days 398 to 536) food was withheld. The eels were kept in seawater, at $23.4^{\circ} \mathrm{C}$. They were marked individually (day 118), and body weight and total body length were measured at intervals. Groups of eels were sacrified at intervals for histological examination of the alimentary tract, weighing of organs and chemical determination of body composition. During the first part of the period of feeding, food intake gradually increased, and the eels grew both in weight and length, their condition index increased, and their strongly atrophied alimentary tract regenerated. When the second maturation was induced, food intake decreased, growth stopped and the alimentary tract underwent atrophy. After the second period of maturation, food intake increased somewhat, and the alimentary tract again regenerated.

A marked increase in eye size was noted as a response upon both the first and the second maturation. The sperm ducts showed a marked dilation at the first sexual maturation and continued to be dilated. Protein and lipid (\%) showed great individual variation, and so did liver weight, but there was a remarkable lack of correlation between these parametres and the rate of growth and the condition index. Furthermore, no correlation existed between the latter two parametres.

The male Anguilla anguilla is not destined to die after spawning and can be led through several successive phases of reproduction and atrophy of the alimentary tract, alternating with phases of feeding, regeneration of the alimentary tract and growth of the body.

## Introduction

The present study was carried out from April 1982 to October 1983 at the Danish Institute for Fisheries and Marine Research.

The background for our experiment was two papers: Fontaine et al., 1982, which mentions a case of food intake by matured silver eels, A. anguilla, and Boëtius \& Boëtius, 1982, in which re-maturation of sexually matured male silver eels A. anguilla is described. The experiment was planned in co-operation with Dr. Lis Olesen Larsen, Zoophysiological Laboratory A, University of Copenhagen, and Dr.s Inge \& Jan Boëtius, the Danish Institute for Fisheries and Marine Research.

## Experimental

The experimental batch consisted of 106 male silver eels, caught when leaving the Baltic for their seaward migration. The eels were brought to the laboratory shortly after capture. On their arrival on October 7,1981 , they were placed in a $1.5 \mathrm{~m}^{3}$ tank. Temperature $14^{\circ} \mathrm{C}$, salinity $28 \%$. The tank was connected to the seawater circuit ( $150 \mathrm{~m}^{3}$ ) in Denmarks Aquarium.

At the start of the experiment, April $15,1982,95$ eels were transferred to a $2 \mathrm{~m}^{3}$ tank with circulating seawater. The temperature throughout the experiment was $23.4 \pm 1.6^{\circ} \mathrm{C}$ and the salinity $28 \% .10$ black PVC tubes ( $57 \times 400 \mathrm{~mm}$ ) were placed in the tank as hiding places for the eels.

As references, 9 male yellow eels were caught on September 7, 1982, in Roskilde Fjord and sacrificed soon after, as well as 10 newly caught male silver eels, which were sacrificed on October 27, 1982.

Eels are numbered in the following way: eels nos 1-9 are yellow, eels nos 10-19 are silver and nos 1-91 are the experimental eels. The number was assigned to the eel on the day it died.

Experimental days were numbered from day 0 (April 15, 1982) to day 536 (October 3, 1983).

The hormone used for sexual maturation was human chorionic gonadotrophin, HCG ('Physex', Leo). Two doses of 500 IU were given intramuscularly at one week's interval. Sexual maturation was induced on days 0 and 7, days 179 and 186 and days 400 and 407 . Approximately three weeks after the first injection the eels were stripped three times at weekly intervals. When an eel failed to give off sperm it was excluded from the experiment as 'negative'. The 15 'negative' eels in the first maturation are excluded both from the experiment and from the primary table. After dissection, however, a few 'negative' eels proved to have matured and they were thus counted as mature in the statistics.

At the start of the feeding experiment (days 118 to 398 ), eels were individually
marked by clippings in the pectoral and anal fins. The food used was krill and Mytilus at a ratio 1:1. Eels were fed every morning after removal of food left over from the day before.

Anaesthesia (immersion in $1.5 \%$ solution of ethylurethane in seawater) was used for body weight and total body length determination on days $0,118,148$, $179,214,365,400$ and 517 , and for checking fin clippings. The reliability of the determinations of body weights and total lengths on anaesthetized eels was checked as follows: 10 control eels were anaesthetized and measured daily during five days. The relative error of the single determination was $\pm 1.7 \%$ for weight and $\pm 0.5 \%$ for length.

Eels for analysis were killed by a prolonged immersion in the ethylurethane solution, and body weights and total lengths were determined. The alimentary tract and liver were removed, cleaned for content and weighed. Tissue samples were taken from oesophagus, stomach and intestine and fixed in Susa-trichloroacetic acid (Heidenhain). The otoliths were then removed and the gutted eel plus the viscera were stored frozen at $-18^{\circ} \mathrm{C}$.

On day 0 and day 118 eels were sampled for analysis by random picking. From day 118 and onward we selected eels in such a way that eels with both low, intermediate and high growth rates were represented, based on our knowledge of the eels' previous growth in the experiment. Eels which died or were killed because of disease or wounds ( 24 eels) were not analysed.

Dates of sampling and number of eels selected for histological and chemical analysis are given below.

|  |  | Day |  |  |  |  |  |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | yellow | silver | 0 | 118 | 179 | 222 | 368 |
| Number chosen for histological analysis | 9 | 10 | 11 | 10 | 10 | 4 | 10 |
| Number chosen for chemical analysis | 6 | 6 | 7 | 6 | 6 | 4 | 6 | 0

Histological investigation of the alimentary tract were made in the following way: the tissue samples were embedded in paraffin, and $6 \mu \mathrm{~m}$ slices were cut and stained in hematoxylin (Ehrlich)-eosin. Measurement of diameter and width of layers were made under a Visopan microscope.

Chemical analysis was made on homogenized whole eels. Homogenates, about 2 grams each, were used for each determination of ash, dry matter, lipid, total nitrogen (N) and non-protein nitrogen (NPN). Samples for ash ( 6 per eel) were dried for 24 hrs at $105^{\circ} \mathrm{C}$ and then heated to $600^{\circ} \mathrm{C}$ for 4 hrs . Samples for dry matter (6) were placed for 24 hrs in an incubator at $40-50^{\circ} \mathrm{C}$ and then for 24 hrs in vacuum desiccator. Lipid analysis (4) was made according to the chloroform/methanol extraction method described by Bligh $\&$ Dyer 1959, followed by centrifuging at 3500 rpm for 30 min . N (3) was determined by Kjeldahls method using a Kjeltex System I equipment. NPN (3) was determined as follows: approximately 2 g homogenate in a volumetric flask was made up to 100 ml with $15 \%$ trichloroacetic acid. After precipitation of protein, 40 ml filtrate was determined for N by Kjeldahl's method. Protein was calculated as $(\mathrm{N}-\mathrm{NPN}) \times 6.025$, the conversion factor adopted from Love 1970 (footnote on p.238).

## Sexual maturation

Results
The maturation stages 1 to 7 (Boëtius $\&$ Boëtius, 1967) was used to describe testicular development in the male eels during artificial maturation.

We succeeded in inducing complete sexual cycles up to three times in individual male eels. The table below indicates the number of eels injected and the number of eels matured during the three experimental periods:

| Days of <br> injections | Number of <br> eels injected | Number of <br> eels matured | Per cent <br> eels matured |
| :---: | :---: | :---: | :---: |
| 0 and 7 | 95 | 86 | 91 |
| 179 and 186 | 46 | 38 | 83 |
| 400 and 407 | 10 | 7 | 70 |

During inspection of developmental stages of the testis, we observed that eels in stage 7 showed a dilation of the vas deferens (sperm ducts), not present in immature eels. Due to this dilation the testicular lobes were dislocated from their original site (close to the body wall) to a more ventral position in the body cavity. This dislocation was most clearly recognized in the dorsolateral region of the airbladder and was observed in all eels which had been through a complete maturation cycle. The difference in size in stage 1 and stage 7 is well demonstrated by injections of contrast fluid (e.g. methyl violet).

## Discussion

It was expected that induction of a second maturation might necessitate a period of starvation before sensitivity to gonadotrophin would develop, because it is known that yellow eels do not respond to gonadotrophin (Boëtius \& Boëtius, 1967). This was not necessary, and an inspection of the eels that matured in the second maturation, showed no relation between growth and the eels' ability to mature.
The tendency to a decline in sensitivity throughout the experiment may not be significant or may reflect some change related to the laboratory conditions or to ageing.

## Feeding

## Results

Fig. 1 shows the eels' daily consumption calculated as ingested food in grams per eel (IF).

From the start of feeding until day 179 the IF increased rapidly. The hormone injections on day 179 and day 186, seemed to suppress the eels' food intake. After stripping the eels for sperm the 'negative' eels were transferred to a separate tank and were fed separately. The 'negative' eels regain their appetite on approximately day 230, the matured eels, however, around day 280 . Hereafter the matured eels show a steady increase in IF, but the increase is not as steep as was the case

abscissa:
$\begin{aligned} & \text { numbers of matured eels } \\ & \text { numbers of 'negative' eels } \\ & \text { (see text for 'negative' eels) }\end{aligned}$

Fig. 1. Food consumption calculated as the difference between quantities of food offered and left over, plotted against time (from day 119 (August 12, 1982) to day 399 (May 19, 1983)). (Note that after the first stripping (day 207) the 46 eels matured in the first maturation are split into two batches fed separately: 26 which matured in the second maturation and 20 'negative'. After the second stripping 8 'negative' eels proved mature.)
between day 118 and day 179 . The IF reaches a level between days 325 and 398 of $1.5-2.0$ grams/eel.

Anaesthesia and/or injections strongly reduces IF for a few days.

## Discussion

The gradual increase in food intake, from when feeding was started until the second gonadotrophin treatment was begun, is correlated with a regeneration of the alimentary tract. The abrupt decline after gonadotrophin injection is probably a result of unspecific reactions to anaesthesia and injections. The period of slowly decreasing food intake until day 220-230 probably reflects processes initiated by gonadotrophin, related to the induced spermatogenesis, since the biological halflife of the hormone is rather short (in toads 3-30 hours, Roos \& Jørgensen 1974). Spermatogenesis was finished around day 222 (see primary table eel nos 46 to 49 all in maturation stage 4). The increasing food intake seen in 'negative' eels at that time may indicate that sexual maturation in those eels only leads to spermatogenesis and not to spermiation. In the matured eels the period of spermiation, which is finished around day 272 (see primary table eels nos $56,57,61$ and 62 in maturation stage 6 or 7), is characterized by a continued low food intake, but then food intake increases again, although not to the level found before the second maturation.

## Growth and condition index

## Results

Body weights and total body lengths of the eels are shown in the primary table and in Fig. 2. In Table 1 the statistical parameters are given.

Table 1. Statistical parameters of experimental eels. G: growth rate, N.S.: not significant, r: correlation coefficient, SD: standard deviation, SE: standard error. Between day 0 and day 118 an ordinary t-test was used to compare mean values, from day 118 and onward a paired $t$-test was used.

Fig. 2. A, body weights versus time. B, total lengths versus time. Vertical lines: range. Horizontal lines: mean. The figures indicate number of eels. White columns: 2 SE values of all eels. Black columns: 2SE values of those eels that survived until next measurement of weights and total lengths.

Between day 0 and day 118 an ordinary t -test was used to compare mean values (we were not able to identify individual eels in this period), from day 118 and onward a paired t -test was used. Due to the narrow range in weights and lengths correlations were calculated from the raw data.

The growth rate of the individual eels ( $G$ ) was defined as follows:

$$
\mathrm{G}=\frac{\text { change in body weight during the period }}{\text { initial body weight } \times \text { number of days in period }} \mathrm{mg} / \mathrm{g} / \text { day }
$$

As a standard expression of an eel's physical proportions we have chosen the condition index ( k ):

$$
\mathrm{k}=\frac{\text { body weight, } \mathrm{g}}{(\text { total length, } \mathrm{cm})^{3}} \times 10^{3}
$$

Day 0 to day 118 (no feeding, 1st maturation). In this period body weights of the eels decreased significantly, whereas their total lengths only showed a slight reduction. The mean of G in this period was $-2.07 \mathrm{mg} / \mathrm{g} / \mathrm{day}$.

Day 118 to day 179 (feeding). The eels in this period showed an increase in both body weights and total lengths. The mean of $G$ is $6.53 \mathrm{mg} / \mathrm{g} / \mathrm{day}$. The maximum G ( $16.39 \mathrm{mg} / \mathrm{g} /$ day) is held by eel no. 77 with a gain in weight from 40 to 80 grams. Eel no. 52 has the minimum $\mathrm{G}(-3.01 \mathrm{mg} / \mathrm{g} /$ day $)$ corresponding to a decrease from 60 to 49 grams. The maximum change in total length is 3.1 cm (an increase of $8.5 \%$ ) obtained by eel no. 72 . None of the eels decrease in length in this period.

Day 179 to day 400 (feeding continued, 2nd maturation). There is a gradual decrease in body weights, whereas total lengths increase until day 214 and then slowly decrease.

Day 400 to day 536 (no feeding, 3 rd maturation). Decrease in both body weights and total lengths is significant. Note that if the period is split into two parts, days 400-517 and days 517-536, a decrease in total length is present in the first period, but an increase in the second. The mean of G in this period was $-1.87 \mathrm{mg} / \mathrm{g} /$ day.

## Discussion

There was a significant growth in weight and length of the body of the fed eels, and the condition index increased in the beginning, but it never reached the initial level and declined in the later part of the feeding period. Condition index did not change in the same pattern as did food intake and the condition of the alimentary tract. Also lipid content and liver weight (see later) do not appear to be related to the nutritional condition.
A calculation of the correlation between the eels' condition index on day 118 and growth rate between day 118 and day 179 gave $r=-0.15$. However the feeding behaviour of the eels was as varied as their rate of growth. The eels left their tubes as soon as food was offered, and after 30 to 45 minutes they would all return to their tubes, even if left over food was present. Some eels fed continuously for up to 45 min . while others snapped food only a few times and still others were seen just to swim around outside the tubes without feeding. There was a great deal of fighting during feeding, but no relation between size and aggression was observed.

Note that the negative growth rate between days 0 and 118 equals the negative growth rate between days 400 and 536 . In these two periods the eels underwent sexual maturation without feeding.

## Alimentary tract and liver

## Results

Fig. 3 shows the gross morphology of the alimentary tract and the sites at which tissue samples were taken. Fig. 4 demonstrates the histological changes. The well developed tract of the yellow eel is only somewhat reduced in the silver eels at the start of the experiment, after a period of starvation of half a year. During the next 118 days of sexual maturation there was a marked atrophy. On day 179 some eels which had grown very little, still had atrophied alimentary tracts, but those which had grown well had regenerated tracts. The histological changes are closely paralleled by changes in weight of the tract (Fig. 5A) (except yellow and silver eels), and growth and weight of the alimentary tract show a positive correlation (Fig. 5C).

The weight changes of the alimentary tract mainly reflect changes in epithelial height and in size of folds. The longitudinal muscle layer is almost unaffected. The circular muscle layer in the intestine is drastically reduced during the first period of starvation and this condition remains unaltered until the conclusion of the experiment.

Fig. 3. Gross morphology of the alimentary tract of the yellow eel. A, B \& C indicate regions where cross sections were made. A, oesophagus; B, stomach; C, intestinc. Modified from Berndt 1938.

Fig. 4. Cross sections of alimentary tracts. Numbers indicate the day of sacrifice. The eels chosen had a gut weight close to the mean of the samples, except on day 179 where eels with minimum and maximum growth are shown. Individual numbers refer to the primary table as follow: Yellow eels: 3, 4, 8. Day 0: $10,9,6$. Day 118: $25,21,23$. Day $179 \mathrm{~min}: 39$, missing, 39. Day 179 max: 44, 44, 43. day 368: 76, 76, 76. Day 536: 91, 91, 91.

Fig. 5. A, weight of alimentary tract in per cent of body weight plotted against time. B, weight of liver in per cent of body weight plotted against time. Circles: individual eels. Horizontal lines: mean. Vertical lines: 2SE. Arrows indicate eels not matured in the third maturation experiment. C, weight of alimentary tract on day 179 versus percentage change in body weight from day 118 to day 179 .

During the periods of starvation and maturation certain characteristic changes in morphology and cell structure were noticed: 1. Heavy reduction in the number of folds in the stomach and in the intestine. 2. Boundaries between tissue layers disintegrate in several layers. 3. Cell to cell adhesion reduces.

The relative liver weight (Fig. 5B) is rather constant throughout the experiment, and only little lower than that of freshly caught yellow and silver eels.

## Discussion

The eels were thus induced to show alternation between a phase dominated by reproduction and a phase dominated by food intake and growth, similar to the spontaneous 'Phasenwechsel' described for the Atlantic salmon by Mishlin 1941.

It may be of interest to note (Peters 1982) that 'stress' in form of 'unavoidable contact with a dominant eel' causes atrophy of the stomach, similar to the one described here during sexual maturation.

## Protein, lipid and water

The data on protein, lipid, water, non-protein nitrogen and ash are given in the primary table. Fig. 6A-E shows the values plotted against time. Fig. 6F shows the calculated residuals ( $\mathrm{R}=100-(\mathrm{W}+\mathrm{L}+\mathrm{P})$ ). The results from freshly caught yellow and silver eels are given for comparison.

The relative amounts of protein and lipid was nearly the same in all examined groups. A strong negative correlation was found for lipid and water ( $\mathrm{r}=-0.97$ ). There was also a negative correlation between condition index and ash content ( $\mathrm{r}=-0.80$ ).

The extent of individual variation can be exemplified by the following figures:

| Growth, days 118 to 179, <br> mg/g/day |  |  | lipid, \% |
| :---: | ---: | :---: | :---: | protein, \%

The low degree of correlation between growth rate and lipid ( $\mathbf{r}=0.27$ ) and between growth rate and protein ( $\mathbf{r}=0.21$ ) of eels analysed from day 179 and onward, underline the large and chance individual variation.

## Eye index and otoliths

## Eye index

As an index of the area covered by the elliptical eye we have chosen the index (I):

$$
I=\frac{\left(\frac{\mathrm{E}_{\mathrm{h}} \times \mathrm{E}_{\mathrm{v}}}{4}\right) \times \pi}{\mathrm{l}_{\mathrm{b}}} \times 100
$$

where $E_{h}$ and $E_{v}$ are horizontal and vertical eye diameters (mm) and $l_{b}$ is the total body length of the eel (mm).

$\%$ (d) uraoud

Fig. 6. Chemical composition of total eels expressed as per cent of body weight at the day of sacrifice plotted against time.
A, protein; B, lipid; C, water; D, non-protein nitrogen; E, ash; F, residue. Circles: individual eels. Horizontal lines: mean. Vertical lines: 2SE.

Fig. 7. Eye index (I) plotted against time. Circles: individual eels. Horizontal lines: mean. Vertical lines: 2SE. Arrows indicate eels not matured in the third maturation experiment.

The data are presented in the primary table and in Fig. 7 (only eels sacrified from day 179 and onward).
During the first period of sexual maturation the eye increases slightly (when the data from non-injected silver eels are used as a reference). Since data for day 118 are lacking we do not know whether the eye changed during the first feeding period between days 118 and 179 .
However, during the second sexual maturation period (days 179 to 222: stage 4) a rapid increase in the eye area takes place. This increase continues to day 368.

During the third sexual maturation period (days 400 to 536) the eyes do not enlarge further, apparently limited by the dimensions of the cranium.

## Otoliths

Otoliths were prepared and examined for possible structures reflecting periods of growth and sexual maturation. No such structures could be identified.

## Concluding remarks

The results of experiments involving feeding and artificial sexual maturation of male silver eels are recapitulated in Fig. 8. Our experiments are given in the frame. The concept of 'Phasenwechsel' is demonstrated in the lower part of the frame.
The postmature feeding eels (day 179) have much in common with the yellow eel. Eels that feed intensively showed the colour of yellow eels and had well
developed alimentary tracts. Moreover these eels were just as aggressive as feeding yellow eels. In two respects, however, our eels differ from yellow eels: their eyes are enlarged and they respond positively to HCG.

Fig. 8. Diagram demonstrating responses of male eels upon HCG and feeding. 1. Male yellow eels do not mature when treated with HCG (Boëtius \& Boëtius 1967). 2. Male silver eels will feed after 6 to 7 months in captivity (Boëtius \& Boëtius 1967). 3. Male silver eels can be matured twice with HCG, without intermediate feeding (Boëtius $\&$ Boëtius 1982). In frame: the present experiment.

A postmature feeding period of two months only resulted in a mean increase in body weight of $40 \%$. A prolonged feeding period with no further induction of sexual maturation would probably have resulted in even larger eels.
The fact that male eels do not die after spermiation and are capable of taking up food and later on re-mature leads us to consider the eel as a potential multibreeder.

## Acknowledgements

The authors wish to thank both the scientific and the technical staff at Zoophysiological Laboratory A, University of Copenhagen, for kind help and advice. Especially they wish to thank Dr. Lis Olesen Larsen for friendly and stimulating discussion and criticism, both during the experiment and in writing the manuscript. They also wish to express their gratitude to Dr. Povl E. Budtz and laboratory technician Susanne Binzer for their kind help in preparing the histological material.

## Notes to primary table

Eels nos 1-9 are yellow and nos 10-19 are silver eels (controls).
Eels nos 1-91 are the experimental eels listed chronologically after time of death. Eels within frames are those chosen for analysis.
Eels outside the frames either died or were killed because of disease or wounds.
Blank means 'no data' and 0 (in column 32) means 'no longitudinal muscle layer present'.

1. no. Eel no.
2. $\mathrm{w}_{\mathrm{b} 118}$ Body weight at day 118 , g.
3. $1_{b 118}$ Total length at day $118, \mathrm{~cm}$.
4. $\mathrm{w}_{\mathrm{b} 148}$ Body weight at day 148 , g.
5. $\mathrm{l}_{\text {b148 }}$ Total length at day $148, \mathrm{~cm}$.
6. $\mathrm{w}_{\mathrm{b} 179}$ Body weight at day 179 , g.
7. $1_{\mathrm{b} 179}$ Total length at day $179, \mathrm{~cm}$.
8. $\mathrm{w}_{\mathrm{b} 214}$ Body weight at day 214 , g.
9. $1_{b 214}$ Total length at day $214, \mathrm{~cm}$.
10. $\mathrm{w}_{\mathrm{b} 365}$ Body weight at day 365 , g.
11. $l_{b 365}$ Total length at day $365, \mathrm{~cm}$.
12. $w_{b 400}$ Body weight at day 400 , $g$.
13. $l_{b 400}$ Total length at day $400, \mathrm{~cm}$.
14. $\mathrm{w}_{\mathrm{b} 517}$ Body weight at day 517 , g.
15. $\mathrm{l}_{\mathrm{b} 517}$ Total length at day $517, \mathrm{~cm}$.
16. date Date of death.
17. day Life-span in days after day 0 (April 15, 1982).
18. $\mathrm{w}_{\mathrm{b}}$ Body weight at death, g .
19. $\mathrm{l}_{\mathrm{b}}$ Total length at death, cm .
20. $\mathrm{w}_{\mathrm{i}}$ Weight of alimentary tract, mg.
21. $w_{l}$ Weight of liver, mg.
22. no. Eel no.
23. stage Stage of maturation. 2nd maturation indicated by one asterisk, 3rd maturation by two asterisks.
24. $\mathrm{E}_{\mathrm{h}}$ Horizontal eye diameter, mm.
25. $\mathrm{E}_{\mathrm{v}}$ Vertical eye diameter, mm.
26. $I_{d} A$ Oesophagus diameter, $\mu \mathrm{m}$.
27. $I_{d} B$ Stomach diameter, $\mu \mathrm{m}$.
28. $\mathrm{I}_{\mathrm{d}} \mathrm{C}$ Intestine diameter, $\mu \mathrm{m}$.
29. $\mathrm{M}_{\mathrm{c}} \mathrm{A}$ Width of circular muscle layer in oesophagus, $\mu \mathrm{m}$.

30: $\mathrm{M}_{\mathrm{c}} \mathrm{B}$ Width of circular muscle layer in stomach, $\mu \mathrm{m}$.
31. $\mathrm{M}_{\mathrm{c}} \mathrm{C}$ Width of circular muscle layer in intestine, $\mu \mathrm{m}$.
32. $\mathrm{M}_{1} \mathrm{~A}$ Width of longitudinal muscle layer in oesophagus, $\mu \mathrm{m}$.
33. $\mathrm{M}_{1} \mathrm{~B}$ Width of longitudinal muscle layer in stomach, $\mu \mathrm{m}$.
34. $\mathrm{M}_{1} \mathrm{C}$ Width of longitudinal muscle layer in intestine, $\mu \mathrm{m}$.
35. EA Width of epithelial layer in oesophagus, $\mu \mathrm{m}$.
36. EB Width of epithelial layer in stomach, $\mu \mathrm{m}$.
37. EC Width of epithelial layer in intestine, $\mu \mathrm{m}$.
38. W Water in per cent of body weight, \%.
39. L Lipid in per cent of body weight, \%.
40. NPN Non-protein nitrogen in per cent of body weight, $\%$.
41. $\mathrm{P} \quad$ Protein in per cent of body weight, \%.
42. A Ash in per cent of body weight, \%.
